ANDROGEN RECEPTOR MODULATOR COMPOUNDS AND METHODS

This application claims priority to U.S. Provisional Application Serial No. 60/150,988, filed August 27, 1999; the entire disclosure of which is incorporated by reference herein.

Field of the Invention

5 This invention relates to non-steroidal compounds that are modulators (i.e. agonists and antagonists) of androgen receptors, and to methods for the making and use of such compounds.

Background of the Invention

Intracellular receptors (IRs) form a class of structurally-related genetic regulators
10 scientists have named "ligand dependent transcription factors." R.M. Evans, *Science*, 240:889 (1988). Steroid receptors are a recognized subset of the IRs, including the progesterone receptor (PR), androgen receptor (AR), estrogen receptor (ER), glucocorticoid receptor (GR) and mineralocorticoid receptor (MR). Regulation of a gene by such factors requires both the IR itself and a corresponding ligand, which has the
15 ability to selectively bind to the IR in a way that affects gene transcription.

Ligands to the IRs can include low molecular weight native molecules, such as the hormones progesterone, estrogen and testosterone, as well as synthetic derivative compounds such as medroxyprogesterone acetate, diethylstilbesterol and 19-nortestosterone. These ligands, when present in the fluid surrounding a cell, pass through
20 the outer cell membrane by passive diffusion and bind to specific IR proteins to create a ligand/receptor complex. This complex then translocates to the cell's nucleus, where it binds to a specific gene or genes present in the cell's DNA. Once bound to DNA, the complex modulates the production of the protein encoded by that gene. In this regard, a compound that binds an IR and mimics the effect of the native ligand is referred to as an
25 "agonist", while a compound that inhibits the effect of the native ligand is called an "antagonist."

Ligands to the steroid receptors are known to play an important role in health of both women and men. For example, the native female ligand, progesterone, as well as synthetic analogues, such as norgestrel (18-homonorethisterone) and norethisterone (17 α -ethinyl-19-nortestosterone), are used in birth control formulations, typically in
5 combination with the female hormone estrogen or synthetic estrogen analogues, as effective modulators of both PR and ER. On the other hand, antagonists to PR are potentially useful in treating chronic disorders, such as certain hormone dependent cancers of the breast, ovaries, and uterus, and in treating non-malignant conditions such as uterine fibroids and endometriosis, a leading cause of infertility in women. Similarly,
10 AR antagonists, such as cyproterone acetate and flutamide, have proved useful in the treatment of prostatic hyperplasia and cancer of the prostate.

The effectiveness of known modulators of steroid receptors is often tempered by their undesired side-effect profile, particularly during long-term administration. For example, the effectiveness of progesterone and estrogen agonists, such as norgestrel and
15 diethylstilbesterol respectively, as female birth control agents must be weighed against the increased risk of breast cancer and heart disease to women taking such agents. Similarly, the progesterone antagonist, mifepristone (RU486), if administered for chronic indications, such as uterine fibroids, endometriosis and certain hormone-dependent cancers, could lead to homeostatic imbalances in a patient due to its inherent cross-
20 reactivity as a GR antagonist. Accordingly, identification of compounds that have good specificity for one or more steroid receptors, but have reduced or no cross-reactivity for other steroid or intracellular receptors, would be of significant value in the treatment of male and female hormone responsive diseases.

A group of quinolinone and coumarin analogs having a fused ring system of the
25 aryl, piperidine, pyrrolidine, or indoline series have been described as androgen modulators. See U. S. Patent No. 5,696,130; Int. Patent Appl. WO 97/49709; L.G. Hamann, *et. al. J. Med. Chem.*, 41:623-639 (1998); J. P. Edwards, *et. al., Bioorg. Med. Chem. Lett.*, 8:745-750 (1998).

In addition, novel enantioselective synthetic routes to *N*-alkyl or *N*-aryl 3,4-
30 dihydro-2*H*-1,4-benzoxazine compounds are described. Such compounds are key intermediates in the preparation of quinolinones and other fused ring structures of the

instant invention. Often, when such fused-ring compounds are chiral and possess biological activity, only one enantiomer is biologically active, or the enantiomers possess different biological activity. Isolating and testing such enantiomers often yields a compound with enhanced selectivity, lower toxicity, and greater potency. Therefore, it would be highly advantageous to selectively prepare these types of compounds in the desired configuration. See Atarashi S., *et al.*, *J. Heterocyclic Chem.*, 28:329 (1991); Xie, L.J., *Chinese Chemical Letters*, 6:857 (1995); Mitscher, L.A., *et al.*, *J. Med. Chem.*, 30:2283 (1987).

The entire disclosures of the publications and references referred to above and hereafter in this specification are incorporated herein by reference.

Summary of the Invention

The present invention is directed to novel compounds, pharmaceutical compositions, and methods for modulating processes mediated by steroid receptors. More particularly, the invention relates to non-steroidal compounds and compositions that are high-affinity, high-specificity agonists, partial agonists (i.e., partial activators and/or tissue-specific activators) and antagonists for the androgen receptor (AR). Also provided are methods of making and using such compounds and pharmaceutical compositions, as well as critical intermediates used in their synthesis.

In another aspect of the invention, a stereoselective synthetic route to intermediate compounds for these AR modulators is described. This aspect of the invention relates to preparing N-alkylated amino alcohol intermediates stereoselectively.

These and various other advantages and features of novelty that characterize the invention are pointed out with particularity in the claims annexed hereto and forming a part hereof. The following detailed description of the invention provides a better understanding of the invention, its advantages, and objects obtained by its use, as well as preferred embodiments of the invention.

Detailed Description of the Invention

Specifically, we have developed high affinity, high specificity agonists, partial agonists (i.e., partial activators and/or tissue-specific activators) and antagonists for the androgen receptor and methods of preparing these compounds and compositions.

In a further preferred aspect, the present invention comprises methods of modulating processes mediated by androgen receptors comprising administering to a
10 patient an effective amount of a compound of the formulas I through VI shown above, wherein R^1 through R^{17} , R^A , V, W, X, Y, Z, m and n all have the same definitions as those given above.

Any of the compounds of the present invention can be synthesized as pharmaceutically acceptable salts for incorporation into various pharmaceutical
15 compositions. As used herein, pharmaceutically acceptable salts include, for example, hydrochloric, hydrobromic, hydroiodic, hydrofluoric, sulfuric, citric, maleic, acetic, lactic, nicotinic, succinic, oxalic, phosphoric, malonic, salicylic, phenylacetic, stearic, pyridine, ammonium, piperazine, diethylamine, nicotinamide, formic, urea, sodium, potassium, calcium, magnesium, zinc, lithium, cinnamic, methylamino, methanesulfonic, picric, tartaric, triethylamino, dimethylamino, and tris(hydroxymethyl)aminomethane.

AR agonist, partial agonist and antagonist compounds (including compounds with tissue-selective AR modulator activity) of the present invention will prove useful in the treatment of acne (antagonist), male-pattern baldness (antagonist), male hormone
25 replacement therapy (agonist), wasting diseases (agonist), hirsutism (antagonist), stimulation of hematopoiesis (agonist), hypogonadism (agonist), prostatic hyperplasia (antagonist), osteoporosis (agonist) male contraception (agonist), impotence (agonist), sexual dysfunction (agonist), cancer cachexia (agonist), various hormone-dependent cancers, including, without limitation, prostate (antagonist) and breast cancer and as
30 anabolic agents (agonist). It is understood by those of skill in the art that a partial agonist

may be used where agonist activity is desired, or where antagonist activity is desired, depending upon the AR modulator profile of the particular partial agonist.

It is understood by those skilled in the art that while the compounds of the present invention will typically be employed as a selective agonists, partial agonists or
5 antagonists, that there may be instances where a compound with a mixed steroid receptor profile is preferred. For example, use of a PR agonist (i.e., progestin) in female contraception often leads to the undesired effects of increased water retention and acne flare-ups. In this instance, a compound that is primarily a PR agonist, but also displays some AR and MR modulating activity, may prove useful. Specifically, the mixed MR
10 effects would be useful to control water balance in the body, while the AR effects would help to control any acne flare-ups that occur.

Furthermore, is understood by those skilled in the art that the compounds of the present invention, including pharmaceutical compositions and formulations containing these compounds, can be used in a wide variety of combination therapies to treat the
15 conditions and diseases described above. Thus, the compounds of the present invention can be used in combination with other hormones and other therapies, including, without limitation, chemotherapeutic agents such as cytostatic and cytotoxic agents, immunological modifiers such as interferons, interleukins, growth hormones and other cytokines, hormone therapies, surgery and radiation therapy.

20 Representative AR modulator compounds (i.e., agonists and antagonists) according to the present invention include:

Scheme I

Compounds of the present invention, comprising classes of heterocyclic nitrogen compounds and their derivatives, can be obtained by routine chemical synthesis by those skilled in the art, e.g., by modification of the heterocyclic nitrogen compounds disclosed or by a total synthesis approach.

The sequences of steps for several general schemes to synthesize the compounds of the present invention are shown below. In each of the schemes the R groups (e.g., R¹,

R², etc.) correspond to the specific substitution patterns noted in the Examples.

However, it will be understood by those skilled in the art that other functionalities disclosed herein at the indicated positions of compounds of formulas I through VI also comprise potential substituents for the analogous positions on the structures within the schemes.

The synthesis of 7*H*-[1,4]oxazino[3,2-*g*]quinolin-7-one compounds (e.g., Structures 6 and 7), is depicted in **Scheme I**. The process of **Scheme I** begins with a cyclization of a haloacetyl halide onto 2-amino-5-nitrophenol (Structure 1) with, for example, chloroacetyl chloride to afford a lactam (Structure 2). See D. R. Shridhar, *et al.*, *Org. Prep. Proc. Int.*, 14:195 (1982). The amide is then reduced to the corresponding amine (Structure 3), with, for example, borane dimethyl sulfide. See Y. Matsumoto, *et al.*, *Chem. Pharm. Bull.*, 44:103-114 (1996). Treatment of a compound such as Structure 3 with an aldehyde or its corresponding hydrate or hemiacetal, for example trifluoroacetaldehyde hydrate in the presence of a reducing agent, for example, sodium cyanoborohydride, in a carboxylic acid, for example trifluoroacetic acid, affords a compound such as Structure 4. The nitro derivative is reduced to the corresponding aniline, with a reducing agent, for example, zinc and calcium chloride, to afford Structure 5. Treatment of the aniline with a β -ketoester or corresponding hydrate, for example 4,4,4-trifluoroacetoacetate, at elevated temperatures, followed by treatment with an acid, for example, sulfuric acid, affords a major product (Structure 6). The cyclization of anilines as described above is known as a Knorr cyclization. See, G. Jones, *Comprehensive Heterocyclic Chemistry*, Katritzky, A. R.; Rees, C. W., eds. Pergamon, New York, 1984. Vol. 2, chap. 2.08, pp 421-426, the disclosure of which is herein incorporated by reference. In turn, the quinolinone nitrogen may be alkylated by, for example, treatment with sodium hydride followed by iodomethane, to afford a compound of Structure 7. Alternatively, a quinolinone compound of Structure 6 can be converted to the corresponding quinoline by treatment with a dehydrating agent, for example, oxyphosphoryl chloride, to afford a compound of Structure 7A.

Alternatively, a quinolinone compound of Structure 6 can be transformed to the corresponding thio-compound by treatment with, for example, Lawesson's reagent [2,4-bis(4-methoxyphenyl)-1,3-dithia-2,4-diphosphetane-2,4-disulfide] to give a 7*H*-

[1,4]oxazino[3,2-g]quinolin-thione (e.g., Structure 8). See J. Voss, *Encyclopedia of Reagents for Organic Synthesis*, Paquette, L. A., Ed. John Wiley and Sons, New York, 1995; Vol. 1, pp 530-533, the disclosure of which is herein incorporated by reference. Alternatively, a compound of Structure 6 (or chiral synthetic precursors of Structure 6) can be separated into its corresponding enantiomers, (+)-6 and (-)-6 by chiral HPLC, with, for example, a preparative Chiralpak AD column eluted with hexanes:isopropanol.

Scheme II

An alternate synthesis of 7H-[1,4]oxazino[3,2-g]quinolin-7-one compounds (e.g., Structures 10 and 11) is shown in Scheme II. The process of Scheme II begins with a Knorr cyclization of 7-amino-3,4-dihydro-4-*p*-methoxybenzyl-2H-1,4-benzoxazine, and a β-ketoester promoted by an acid, for example, sulfuric acid to afford a compound of Structure 10. Alkylation of the quinolinone nitrogen may be achieved by treatment with an aldehyde or its corresponding hydrate, for example cyclopropanecarboxaldehyde in the presence of a reducing agent, for example, sodium cyanoborohydride, to afford the alkylated derivative of the corresponding quinolinone compound (e.g., Structure 11).

Scheme III

An additional synthetic route into quinoline compounds (e.g., Structures 16 and 18) is shown in **Scheme III**. The process of **Scheme III** begins with reductive amination of 2-methoxy-4-nitroaniline with an aldehyde or its corresponding hydrate, for example trifluoroacetaldehyde hydrate in the presence of a reducing agent, for example, sodium cyanoborohydride, in an acid, for example trifluoroacetic acid, to afford the

corresponding *N*-alkylated amine. The nitro derivative is reduced to the corresponding aniline, with a reducing agent, for example, zinc and calcium chloride, to afford a compound of Structure 13. Knorr cyclization of the aniline by heating with a β -ketoester or corresponding hydrate, for example 4,4,4-trifluoroacetoacetate, followed by treatment with an acid, for example, sulfuric acid, affords a product of Structure 14. Protection of the pyridone ring, with, for example isopropyl iodide mediated by a base, for example, cesium fluoride, affords the corresponding imino ether. See T. Sato, *et al.*, *Synlett* **1995**, 845-846. Demethylation of the anisole is accomplished by treatment with, for example, sodium thiophenolate to afford a compound of Structure 15. See C. Hansson, *et al.*, *Synthesis* **1975**, 191. Treatment of aminophenol derivative 15 with an α -bromoester, for example, ethyl bromoacetate, and a base, with for example, potassium carbonate, affords a quinolinone compound (Structure 16). Treatment of quinolinone compounds such as Structure 16 with an alkylidenation reagent, for example, Tebbe's reagent, followed by reduction with, for example, sodium cyanoborohydride, in an acid, for example acetic acid, affords a quinoline compound (e.g., Structure 17). See S. H. Pine, *et al.*, *J. Org. Chem.* **1985**, 50, 1212, for the methylenation of amides. Deprotection can be accomplished in one of two ways. Treatment of the iminoether (Structure 17) with a mineral acid, for example hydrochloric acid, affords a 7*H*-[1,4]oxazino[3,2-*g*]quinolin-7-one compound (Structure 18). Alternatively, this transformation can be carried out with a Lewis acid, for example boron trichloride, to afford Structure 18. See T. Sala, *et al.*, *J. Chem. Soc., Perkin Trans. I*, **1979**, 2593. Quinolinone compounds of Structure 18 (or any chiral synthetic precursor of 18) can be separated into their corresponding enantiomers, (+)-18 and (-)-18 by chiral HPLC, with, for example, a preparative Chiralpak AD column eluted with hexanes:isopropanol.

Scheme IV

- The process of converting quinolinone compounds (e.g., Structure 16) into corresponding hydroxyalkyl quinoline compounds (e.g., Structure 19) and then further converting into corresponding hydroxyalkyl, acyloxyalkyl, and alkyloxyalkyl quinolinone derivatives (e.g., Structures 20, 21, and 23 respectively) is shown in Scheme IV. The process of Scheme IV begins with a Tebbe olefination of a quinolinone compound (e.g., Structure 16) followed by hydroboration of the resultant enamine to afford a hydroxyalkyl quinoline compound (Structure 19). See C. T. Goralski, *et. al. Tetrahedron Lett.* 1994, 35, 3251, for the hydroboration of enamines. Hydrolysis of the imino ether with an acid, for example hydrochloric acid, affords a hydroxy quinolinone compound (e.g., Structure 20).

Alternatively, hydrolysis of the imino ether of a hydroxyalkyl quinoline compound (e.g., Structure 19) can be carried out with an acid, for example hydrochloric acid, in acetic acid, to afford an acyloxyalkyl quinolinone compound (Structure 21)

Alternatively, a hydroxy quinoline compound (e.g., Structure 19) can be *O*-alkylated by treatment with a base, for example, sodium hydride, and an alkylating agent, with, for example methyl iodide, to afford an alkoxyalkyl quinoline compound (e.g., Structure 22). Imino ether hydrolysis of Structure 22 with an acid, for example hydrochloric acid in acetic acid, affords an alkoxyalkyl quinoline compound (Structure 23). Compound such as Structures 20, 21, or 23 can be separated into their corresponding enantiomers, (+)-20 and (-)-20, (+)-21 and (-)-21, or (+)-23 and (-)-23 by chiral HPLC, with, for example, a preparative Chiralpak AD column eluted with hexanes:isopropanol.

Scheme V

Quinolinone compounds (e.g., Structure 16) may be converted into corresponding quinoline-diones (e.g., Structure 24), hydroxy quinolinones (e.g., Structure 25), and quinoline-thiones (e.g., Structures 26 and 27) by the processes shown in Scheme V. The process of Scheme V begins with the deprotection of the imino ether of Structure 16 by treatment with a mineral acid, for example, hydrochloric acid, to afford a quinoline-dione compound of Structure 24. Alternatively, this transformation can be carried out with a Lewis acid, for example, boron trichloride, to afford a quinoline-dione compound (e.g., Structure 24). See T. Sala, et al., *supra*. A quinoline-dione compound (e.g., Structure

24) can be converted to a hydroxy quinoline compound (e.g., Structure 25) by addition of an organometallic reagent, for example, methyl lithium, which affords a hydroxy quinoline compound (Structure 25).

Quinoline compounds (e.g., Structure 16) can optionally be converted into corresponding thio-compounds (e.g., Structure 25) by treatment with, for example, Lawesson's reagent [2,4-bis(4-methoxyphenyl)-1,3-dithia-2,4-diphosphetane-2,4-disulfide]. Hydrolysis of the imino ether with a Lewis acid, for example, boron trichloride, affords a quinoline-thione compound (Structure 26).

Scheme VI

A synthesis of quinolinone compounds such as Structure 30 is shown in Scheme VI. The process of Scheme VI begins with the O-alkylation of an o-aminophenol, for example, a 6-amino-7-hydroxyquinoline, with a haloketone, for example, chloroacetone, mediated by a base, for example, potassium carbonate, followed by treatment with a reducing agent, for example, sodium cyanoborohydride, in an acid, for example, acetic acid, to afford a quinoline compound of Structure 29. Hydrolysis of the imino ether of Structure 29 with an acid, for example, hydrochloric acid in acetic acid, affords a quinolinone compound of Structure 30. Alkylation of the quinolinone nitrogen is achieved by treatment of quinolinone compounds (e.g., Structure 30) with an aldehyde or its corresponding hydrate, for example, cyclopropanecarboxaldehyde, with a reducing agent, for example, sodium cyanoborohydride, in an acid, for example, acetic acid, affords a compound of Structure 31.

Scheme VIA

- An additional route to quinolinone compounds such as Structure 31D is shown in Scheme VIA. The process of Scheme VIA begins with the alkylation of a 6-aminoquinolinone with, for example, 6-amino-7-methoxy-4-trifluoromethyl-1*H*-quinolin-2-one, with an alkyl halide, for example, isopropyl iodide, mediated by a base, for example, cesium fluoride, to afford a compound of structure 31B. Demethylation of the methyl ether is accomplished by treatment with, for example, sodium thiophenolate to afford a compound of Structure 31C. Annulation of the oxazine ring can be accomplished by treatment with a vicinal dihalide, for example, 1,2-dibromoethane, mediated by a base, for example potassium carbonate, to afford the corresponding 1,4-oxazine, which in turn is converted to a compound of Structure 31D by treatment with an acid, for example, hydrochloric acid in acetic acid at elevated temperatures.

Scheme VII

Quinolinones (e.g., Structure 35) are prepared from benzoxazines (e.g., Structure 34) by the synthetic route outlined in Scheme VII. Scheme VII begins with an alkylation of a haloketone onto 2-amino-5-nitrophenol (Structure 1) with, for example, 2-bromobutanone, mediated by a base, for example, potassium carbonate, followed by treatment with a reducing agent, for example, sodium cyanoborohydride, in an acid, for example acetic acid, to afford a benzoxazine compound (e.g., Structure 32). The benzoxazine is alkylated at the benzoxazine nitrogen by treatment of a benzoxazine compound (e.g., Structure 32) with an aldehyde, its corresponding hydrate or hemiacetal, with for example, trifluoroacetaldehyde hydrate in the presence of a reducing agent, for example, sodium cyanoborohydride, in an acid, for example trifluoroacetic acid. This procedure affords an alkylated benzoxazine compound (e.g., Structure 33). The nitro derivative of the alkylated benzoxazine compound (Structure 33) is reduced to the corresponding aniline by catalytic hydrogenation or with a reducing agent, for example, zinc and calcium chloride, to afford benzoxazine compound (e.g., Structure 34). Knorr cyclization of an aminobenzoxazine (e.g., Structure 34) by heating with a β -ketoester or

corresponding hydrate, with for example, 4,4,4-trifluoroacetoacetate, followed by treatment with an acid, for example, sulfuric acid, affords a quinolinone product (e.g., Structure 35).

Scheme VIIA

Compounds such as the 3,4-dihydro-7-nitro-2*H*-1,4-benzoxazines of Structure **33** are key intermediates in the preparation of quinolinones and other fused ring structures. In accordance with the current invention, we have developed a method to prepare these 3,4-dihydro-7-nitro-2*H*-1,4-benzoxazines in enantiomerically pure form (Structure **39**) from optically pure β -aminoalcohols. A synthetic method for the preparation of enantiomerically pure, fused ring compounds, such as quinolinones **41**, that relies upon such intermediates is shown in **Scheme VIII**.

Scheme VIII

- The asymmetric synthesis of **Scheme VIII** begins with the chemo- and regioselective *N*-alkylation of a β -aminoalcohol, either as a single enantiomer (*R* or *S*) or its racemate, for example, (*R*)-2-amino-1-propanol, onto a 3,4-dihalono-
 5 nitrobenzene, for example, 3,4-difluoronitrobenzene, mediated by a base, for example, sodium bicarbonate, affords an optically pure arylamino alcohol (e.g., Structure 36). Treatment of amino alcohol compounds such as Structure 36 with an aldehyde or the corresponding hydrate or hemiacetal, for example, trifluoroacetaldehyde ethyl hemiacetal, in the presence of an
 10 acid catalyst, for example *p*-toluenesulfonic acid, affords an optically pure oxazolidine compound (e.g., Structure 37). Treatment of an oxazolidine compound such as Structure 37 with a reducing agent, for example, triethylsilane, in the presence of an acid, for example, boron trifluoride etherate, affords an *N*-alkyl substituted amino alcohol compound (e.g., Structure 38). Benzoxazine compounds (e.g., Structure 39), may then be
 15 formed by cyclization of the *N*-alkyl substituted amino alcohol compounds (e.g.,

Structure 38) by treatment with a base such as sodium hydride. Reduction of nitro benzoxazine compounds (e.g., Structure 39) with a reducing agent, for example, zinc and calcium chloride affords an amino benzoxazine compound (e.g., Structure 40). Treatment of an amino benzoxazine with a β -ketoester or its corresponding hydrate, for example ethyl 4,4,4-trifluoroacetoacetate, at elevated temperatures, affords the corresponding acetanilide. Treatment of the acetanilide with an acid, for example, sulfuric acid, affords an optically pure quinolinone compound (e.g., Structure 41). An enantiomer of Structure 41, or a racemic mixture may be obtained by the synthetic route as described in Scheme VIII, by starting with the enantiomer of the β -aminoalcohol as shown (e.g., an (*S*)- β -amino alcohol), or a racemic mixture of the β -aminoalcohol shown (e.g., a (\pm)- β -amino alcohol). Accordingly, an (*S*)- β -amino alcohol, employed in Scheme VII, produces an (*S*)-quinolinone, an (*R*)- β -amino alcohol, employed in Scheme VII, produces an (*R*)-quinolinone, and a racemic mixture of the β -amino alcohol, employed in Scheme VII, produces a racemic mixture of the corresponding quinolinone.

Introduction of an *N*-alkyl or *N*-methylaryl group through the reductive cleavage of oxazolidine 37, as outlined in Scheme VIII, is generally applicable to the preparation of enantiomerically pure arylamino alcohol compounds such as Structure 38. Furthermore, the introduction of an *N*-(2-haloethyl) group through the reductive cleavage of an aryl oxazolidine is a novel process that has general utility in organic synthesis.

Preparation of *N*-Alkyl or *N*-Methylaryl Arylamino Alcohols

In the above process sequence, R^{4-7} may optionally represent hydrogen or alkyl or aryl groups, including $\text{C}_1 - \text{C}_8$ alkyl, $\text{C}_3 - \text{C}_8$ cycloalkyl, $\text{C}_1 - \text{C}_8$ heteroalkyl, $\text{C}_1 - \text{C}_8$ haloalkyl, aryl, arylalkyl, heteroaryl, $\text{C}_2 - \text{C}_8$ alkynyl, or $\text{C}_2 - \text{C}_8$ alkenyl and wherein the

alkyl, cycloalkyl, heteroalkyl, haloalkyl, aryl, arylalkyl, heteroaryl, alkynyl, and alkenyl are optionally substituted with halogen, C₁ – C₄ alkyl, or C₁ – C₄ haloalkyl;

R^x may represent C₁ – C₈ alkyl, C₃ – C₈ cycloalkyl, C₁ – C₈ heteroalkyl, C₁ – C₈ haloalkyl, allyl, aryl, arylalkyl, heteroaryl, C₂ – C₈ alkynyl, or C₂ – C₈ alkenyl and
 5 wherein the alkyl, cycloalkyl, heteroalkyl, haloalkyl, allyl, aryl, arylalkyl, heteroaryl, alkynyl, and alkenyl are optionally substituted with halogen, C₁ – C₄ alkyl, or C₁ – C₄ haloalkyl.

Ar represents optionally substituted aryl or heteroaryl groups, including mono- and polycyclic structures, optionally substituted at one or more positions.

10 Additional substitutions are also possible and can be readily determined by one skilled in the art.

The above process sequence begins with an arylamino alcohol which is then converted into an oxazolidine with an aldehyde or the corresponding hydrate or hemiacetal in the presence of an acid catalyst. The oxazolidine is then converted to an *N*-alkylaryl amino alcohol by addition of a reducing agent such as triethylsilane or sodium
 15 cyanoborohydride in the presence of a Lewis acid such as boron trifluoride etherate or a protic acid such as trifluoroacetic acid as a catalyst. Additional aldehydes and their corresponding hydrates as well as reducing agents may be used and are readily determined by those skilled in the art.

Scheme IX

Scheme IX describes an alternative to the route of **Scheme VIII** for formation of enantiomerically pure benzoxazine compounds such as Structure 39. The route of

Scheme IX offers direct access to compounds of Structure 39 in which R^4 and R^{13} taken together form a ring structure. The process of **Scheme IX** begins with reaction of a secondary aminoalcohol, either a single enantiomer (*R* or *S*) or its racemate, for example 2-piperidinemethanol, with a 3,4-dihalonitrobenzene, for example, 3,4-

- 5 difluoronitrobenzene, to afford an *N*-aryl substituted tertiary aminoalcohol compound such as Structure 42. Cyclization of Structure 42, mediated by treatment with a base, for example, sodium hydride, affords a benzoxazine compound (e.g., Structure 39).

Benzoxazine compounds such as Structure 39 may then further be employed in the synthesis of quinolinone compounds as described herein.

Scheme X

10

- Pyrazino-quinolinone compounds (e.g., Structure 49) may be prepared by the process described in **Scheme X**. The process of **Scheme X** begins with the alkylation of a 1,2-phenylenediamine, for example, 1,2-phenylenediamine, with an α -haloester, for example ethyl 2-bromoisobutyrate, mediated by a base, for example diisopropylethylamine, to afford a compound of Structure 44. Nitration of 44 with, for
- 15 example, nitric acid in sulfuric acid, affords a compound of Structure 45. The nitro group

of 45 can be reduced to the corresponding aniline, with, for example, palladium on carbon under a hydrogen atmosphere, to afford a compound of Structure 46. Treatment of the aniline with a β -ketoester or its corresponding hydrate, for example 4,4,4-trifluoroacetoacetate, at elevated temperatures, affords the corresponding acetanilide.

- 5 Treatment of the acetanilide with an acid, for example, sulfuric acid, affords a compound of Structure 47. Protection of the pyridone ring, with, for example isopropyl iodide mediated by a base, for example, cesium fluoride, affords the corresponding imino ether (Structure 48). Reduction of the amide with, for example, borane dimethyl sulfide, affords the corresponding amine. Hydrolysis of this imino ether with an acid, for
- 10 example, hydrochloric acid in acetic acid, affords a pyrazino-quinolinone compound such as Structure 49.

Scheme XI

- Thiazino-quinolinone compounds (e.g., Structure 56) are prepared as shown in **Scheme XI**. The process of **Scheme XI** begins with the treatment of an aniline, for example, 4-bromo-3-chloroaniline, with a β -ketoester or its corresponding hydrate, for example 4,4,4-trifluoroacetoacetate, at elevated temperatures, to afford the corresponding acetanilide. Treatment of the acetanilide with an acid, for example, sulfuric acid, affords the corresponding 1*H*-quinolin-2-one (an example of a Knorr cyclization as described further herein). Protection of the pyridone ring, with, for example, isopropyl iodide, mediated by a base, for example, cesium fluoride, affords a compound of Structure 51. Treatment of a compound (e.g., Structure 51) with a β -aminothiol, for example, 2-

aminoethanethiol hydrochloride, mediated by a base, for example, sodium hydride, affords a compound of Structure 52. Treatment of a compound of Structure 52 with a ligated transition metal, for example palladium acetate and BINAP, in the presence of a base, for example sodium *t*-butoxide, at elevated temperatures, affords a compound of Structure 53. See S. Wagaw, *et al.*, *J. Am. Chem. Soc.* **1997**, *119*, 8451-8458. Treatment of a compound of Structure 53 with an aldehyde or its corresponding hydrate or hemiacetal, for example, formaldehyde, affords a compound of Structure 55. Hydrolysis of the imino ether can be accomplished by treatment of a compound of Structure 55 with an acid, for example hydrochloric acid, at elevated temperatures, to afford a thiazino-quinolinone compound such as Structure 56. Alternatively, a compound of Structure 53 can be deprotected with an acid, for example hydrochloric acid, at elevated temperatures, to afford a thiazino-quinolinone compound such as Structure 54.

The compounds of the present invention also include racemates, stereoisomers and mixtures of said compounds, including isotopically-labeled and radio-labeled compounds. Such isomers can be isolated by standard resolution techniques, including fractional crystallization and chiral column chromatography.

As noted above, any of the steroid modulator compounds of the present invention can be combined in a mixture with a pharmaceutically acceptable carrier to provide pharmaceutical compositions useful for treating the biological conditions or disorders noted herein in mammalian, and more preferably, in human patients. The particular carrier employed in these pharmaceutical compositions may take a wide variety of forms depending upon the type of administration desired, e.g., intravenous, oral, topical, suppository or parenteral.

In preparing the compositions in oral liquid dosage forms (e.g., suspensions, elixirs and solutions), typical pharmaceutical media, such as water, glycols, oils, alcohols, flavoring agents, preservatives, coloring agents and the like can be employed. Similarly, when preparing oral solid dosage forms (e.g., powders, tablets and capsules), carriers such as starches, sugars, diluents, granulating agents, lubricants, binders, disintegrating agents and the like will be employed. Due to their ease of administration, tablets and capsules represent the most advantageous oral dosage form for the pharmaceutical compositions of the present invention.

For parenteral administration, the carrier will typically comprise sterile water, although other ingredients that aid in solubility or serve as preservatives, may also be included. Furthermore, injectable suspensions may also be prepared, in which case appropriate liquid carriers, suspending agents and the like will be employed.

5 For topical administration, the compounds of the present invention may be formulated using bland, moisturizing bases, such as ointments or creams. Examples of suitable ointment bases are petrolatum, petrolatum plus volatile silicones, lanolin, and water in oil emulsions such as Eucerin™ (Beiersdorf). Examples of suitable cream bases are Nivea™ Cream (Beiersdorf), cold cream (USP), Purpose Cream™ (Johnson &
10 Johnson), hydrophilic ointment (USP), and Lubriderm™ (Warner-Lambert).

The pharmaceutical compositions and compounds of the present invention will generally be administered in the form of a dosage unit (e.g., tablet, capsule etc.) at from about 1 µg/kg of body weight to about 500 mg/kg of body weight, more preferably from about 10 µg/kg to about 250 mg/kg, and most preferably from about 20 µg/kg to about
15 100 mg/kg. As recognized by those skilled in the art, the particular quantity of pharmaceutical composition according to the present invention administered to a patient will depend upon a number of factors, including, without limitation, the biological activity desired, the condition of the patient, and tolerance for the drug.

The compounds of this invention also have utility when radio- or isotopically-
20 labeled as ligands for use in assays to determine the presence of AR in a cell background or extract. They are particularly useful due to their ability to selectively activate androgen receptors, and can therefore be used to determine the presence of such receptors in the presence of other steroid receptors or related intracellular receptors.

Due to the selective specificity of the compounds of this invention for steroid
25 receptors, these compounds can be used to purify samples of steroid receptors *in vitro*. Such purification can be carried out by mixing samples containing steroid receptors with one or more of the compounds of the present invention so that the compounds bind to the receptors of choice, and then separating out the bound ligand/receptor combination by separation techniques which are known to those of skill in the art. These techniques
30 include column separation, filtration, centrifugation, tagging and physical separation, and antibody complexing, among others.

The compounds and pharmaceutical compositions of the present invention can advantageously be used in the treatment of the diseases and conditions described herein. In this regard, the compounds and compositions of the present invention will prove particularly useful as modulators of male sex steroid-dependent diseases and conditions
5 such as the treatment of acne, male-pattern baldness, male hormone replacement therapy, sexual dysfunction, wasting diseases, hirsutism, stimulation of hematopoiesis, hypogonadism, prostatic hyperplasia, osteoporosis, male contraception, impotence, cancer cachexia, various hormone-dependent cancers, including, without limitation, prostate and breast cancer and as anabolic agents.

10 The compounds and pharmaceutical compositions of the present invention possess a number of advantages over previously identified steroidal and non-steroidal compounds.

Furthermore, the compounds and pharmaceutical compositions of the present invention possess a number of advantages over previously identified steroid modulator
15 compounds. For example, the compounds are extremely potent activators of AR, preferably displaying 50% maximal activation of AR at a concentration of less than 100 nM, more preferably at a concentration of less than 50 nM, more preferably yet at a concentration of less than 20 nM, and most preferably at a concentration of 10 nM or less. Also, the selective compounds of the present invention generally do not display
20 undesired cross-reactivity with other steroid receptors, as is seen with the compound mifepristone (RU486; Roussel Uclaf), a known PR antagonist that displays an undesirable cross reactivity on GR and AR, thereby limiting its use in long-term, chronic administration. In addition, the compounds of the present invention, as small organic molecules, are easier to synthesize, provide greater stability and can be more easily
25 administered in oral dosage forms than other known steroidal compounds.

The invention will be further illustrated by reference to the following non-limiting Examples.

General Method 9: Resolution of Compounds of Structure 6, 18, or 23 to their corresponding enantiomers via chiral HPLC. A preparative Chiralpak AD column (10 μm particle size, 20 x 250 mm OR 10 x 250 mm, Daicel Chemical Industries, Ltd.) on a Beckman Gold HPLC was equilibrated with an eluent of hexanes:isopropanol at a flow rate of 4.5-5 mL/min. EXAMPLE 56

15 Steroid Receptor Activity

Utilizing the "cis-trans" or "co-transfection" assay described by Evans et al.,
Science, 240:889-95 (May 13, 1988), the disclosure of which is herein incorporated by
reference, the compounds of the present invention were tested and found to have strong,
specific activity as both agonists, partial agonists and antagonists of AR. This assay is
20 described in further detail in U.S. Patent Nos. 4,981,784 and 5,071,773, the disclosures of
which are incorporated herein by reference.

The co-transfection assay provides a method for identifying functional agonists
and partial agonists that mimic, or antagonists that inhibit, the effect of native hormones,
and quantifying their activity for responsive IR proteins. In this regard, the co-
25 transfection assay mimics an *in vivo* system in the laboratory. Importantly, activity in the
co-transfection assay correlates very well with known *in vivo* activity, such that the co-
transfection assay functions as a qualitative and quantitative predictor of a tested
compounds *in vivo* pharmacology. See, e.g., T. Berger et al. 41 *J. Steroid Biochem.*
Molec. Biol. 773 (1992), the disclosure of which is herein incorporated by reference.

In the co-transfection assay, a cloned cDNA for an IR (e.g., human PR, AR or GR) under the control of a constitutive promoter (e.g., the SV 40 promoter) is introduced by transfection (a procedure to induce cells to take up foreign genes) into a background cell substantially devoid of endogenous IRs. This introduced gene directs the recipient
5 cells to make the IR protein of interest. A second gene is also introduced (co-transfected) into the same cells in conjunction with the IR gene. This second gene, comprising the cDNA for a reporter protein, such as firefly luciferase (LUC), controlled by an appropriate hormone responsive promoter containing a hormone response element (HRE). This reporter plasmid functions as a reporter for the transcription-modulating
10 activity of the target IR. Thus, the reporter acts as a surrogate for the products (mRNA then protein) normally expressed by a gene under control of the target receptor and its native hormone.

The co-transfection assay can detect small molecule agonists or antagonists of target IRs. Exposing the transfected cells to an agonist ligand compound increases
15 reporter activity in the transfected cells. This activity can be conveniently measured, e.g., by increasing luciferase production, which reflects compound-dependent, IR-mediated increases in reporter transcription. To detect antagonists, the co-transfection assay is carried out in the presence of a constant concentration of an agonist to the target IR (e.g., progesterone for PR) known to induce a defined reporter signal. Increasing
20 concentrations of a suspected antagonist will decrease the reporter signal (e.g., luciferase production). The co-transfection assay is therefore useful to detect both agonists and antagonists of specific IRs. Furthermore, it determines not only whether a compound interacts with a particular IR, but whether this interaction mimics (agonizes) or blocks (antagonizes) the effects of the native regulatory molecules on target gene expression, as
25 well as the specificity and strength of this interaction.

The activity of selected steroid receptor modulator compounds of the present invention were evaluated utilizing the co-transfection assay, and in standard IR binding assays, according to the following illustrative Examples.

Co-transfection assay

30 CV-1 cells (African green monkey kidney fibroblasts) were cultured in the presence of Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10%

charcoal resin-stripped fetal bovine serum (CH-FBS) then transferred to 96-well microtiter plates one day prior to transfection.

To determine AR agonist and antagonist activity of the compounds of the present invention, the CV-1 cells were transiently transfected by calcium phosphate coprecipitation according to the procedure of Berger et al., 41 *J. Steroid Biochem. Mol. Biol.*, 733 (1992) with the following plasmids: pRShAR (5 ng/well), MTV-LUC reporter (100 ng/well), pRS- β -Gal (50 ng/well) and filler DNA (pGEM; 45 ng/well). The receptor plasmid, pRShAR, contains the human AR under constitutive control of the SV-40 promoter, as more fully described in J.A. Simental et al., "Transcriptional activation and nuclear targeting signals of the human androgen receptor", 266 *J. Biol. Chem.*, 510 (1991).

The reporter plasmid, MTV-LUC, contains the cDNA for firefly luciferase (LUC) under control of the mouse mammary tumor virus (MTV) long terminal repeat, a conditional promoter containing an androgen response element. See e.g., Berger et al. *supra*. In addition, pRS- β -Gal, coding for constitutive expression of *E. coli* β -galactosidase (β -Gal), was included as an internal control for evaluation of transfection efficiency and compound toxicity.

Six hours after transfection, media was removed and the cells were washed with phosphate-buffered saline (PBS). Media containing reference compounds (i.e. progesterone as a PR agonist, mifepristone ((11 β ,17 β)-11-[4-(dimethylamino)phenyl]-17-hydroxy-17-(1-propynyl)estra-4,9-dien-3-one: RU486; Roussel Uclaf) as a PR antagonist; dihydrotestosterone (DHT; Sigma Chemical) as an AR agonist and 2-OH-flutamide (the active metabolite of 2-methyl-N-[4-nitro-3-(trifluoromethyl)phenyl]pronanamide; Schering-Plough) as an AR antagonist; estradiol (Sigma) as an ER agonist and ICI 164,384 (N-butyl-3,17-dihydroxy-N-methyl-(7- α ,17- β)-estra-1,3,5(10)-triene-7-undecanamide; ICI Americas) as an ER antagonist; dexamethasone (Sigma) as a GR agonist and RU486 as a GR antagonist; and aldosterone (Sigma) as a MR agonist and spironolactone ((7- α -[acetylthio]-17- α -hydroxy-3-oxopregn-4-ene-21-carboxylic acid gamma-lactone; Sigma) as an MR antagonist) and/or the modulator compounds of the present invention in concentrations ranging from 10^{-12} to 10^{-5} M were added to the cells. Three to four replicates were used

for each sample. Transfections and subsequent procedures were performed on a Biomek 1000 automated laboratory work station.

After 40 hours, the cells were washed with PBS, lysed with a Triton X-100-based buffer and assayed for LUC and β -Gal activities using a luminometer or spectrophotometer, respectively. For each replicate, the normalized response (NR) was calculated as:

$$\text{LUC response}/\beta\text{-Gal rate}$$

where β -Gal rate = β -Gal/ β -Gal incubation time.

The mean and standard error of the mean (SEM) of the NR were calculated. Data was plotted as the response of the compound compared to the reference compounds over the range of the dose-response curve. For agonist experiments, the effective concentration that produced 50% of the maximum response (EC₅₀) was quantified.

Agonist efficacy was a function (%) of LUC expression relative to the maximum LUC production by the reference agonist for PR, AR, ER, GR or MR. Antagonist activity was determined by testing the amount of LUC expression in the presence of a fixed amount of DHT as an AR agonist and progesterone as a PR agonist at the EC₅₀ concentration. The concentration of test compound that inhibited 50% of LUC expression induced by the reference agonist was quantified (IC₅₀). In addition, the efficacy of antagonists was determined as a function (%) of maximal inhibition.

EXAMPLE -57

- 10 The activity of selected compounds of the present invention as AR agonists was investigated in an immature castrated male rat model, a recognized test of the androgen activity of a given compound, as described in L. G. Hershberger et al., "Myotrophic Activity of 19-Nortestosterone and Other Steroids Determined by Modified Levator Ani Muscle Method" 83 *Proc. Soc. Exptl. Biol. Med.*, 175 (1953), and P. C. Walsh and R. F.

Gittes, "Inhibition of extratesticular stimuli to prostatic growth in the castrated rat by antiandrogens", 86 *Endocrinology*, 624 (1970); the disclosures of which are herein incorporated by reference.

The basis of this assay is the fact that the male sexual accessory organs, such as the prostate and seminal vesicles, play an important role in reproductive function. These glands are stimulated to grow and are maintained in size and secretory function by the continued presence of serum testosterone (T), which is the major serum androgen (>95%) produced by the Leydig cells in the testis under the control of the pituitary luteinizing hormone (LH) and follicle stimulating hormone (FSH). Testosterone is converted to the more active form, dihydrotestosterone (DHT), within the prostate by 5-alpha-reductase. Adrenal androgens also contribute about 20% of total DHT in the rat prostate, and about 40% of that in 65-year-old men. F. Labrie et al. 16 *Clin. Invest. Med.*, 475–492 (1993). However, this is not a major pathway, since in both animals and humans, castration leads to almost complete involution of the prostate and seminal vesicles without concomitant adrenalectomy. Therefore, under normal conditions, the adrenals do not support significant growth of prostatic tissue. M. C. Luke and D. S. Coffey, "The Physiology of Reproduction" ed. by E. Knobil and J. D. Neill, 1, 1435–1487 (1994). Since the male sex organs are the tissues most responsive to modulation of androgen activity, this model is used to determine the androgen-dependent growth of the sex accessory organs in immature castrated rats. In addition to the prostate and seminal vesicles, the levator ani demonstrates androgen dependent growth (Herschberger, *supra*). Androgens which show the greatest levator ani growth also show the greatest anabolic activity by nitrogen retention methods. Hence, the levator ani is a useful endpoint to measure myotrophic effects on muscle. Compounds which show anabolic activities could be useful in the treatment of muscle-wasting disorders. Further, compounds which possess such anabolic activity without concomitant androgenic activity (tissue selectivity) would be of practical therapeutic value. Male immature rats (50–60 g, 21-day-old, Sprague-Dawley, Harlan) were castrated under metofane anesthesia. Immediately after surgery, animals groups were dosed for 3 days as follows:

- (1) control vehicle;
- (2) Fluoxymesterone (Fluox) (1.0, 3.0, and 100 mg/kg, oral administration daily); and

(3) a compound of the present invention (different doses, oral administration daily) to demonstrate agonist activity

At the end of the 3-day treatment, the animals were sacrificed, and the ventral prostates (VP), seminal vesicles (SV), and levator ani (LA) were collected and weighed.

5 The sexual organ weights were first standardized as mg per 100 g of body weight, and the increase in organ weight induced by the compounds of the present invention was compared to the castrate control animals. The organ weight of the intact control animals is considered fully efficacious (100%). Super-anova (one factor) was used for statistical analysis.

10 The gain and loss of sexual organ weights reflect the changes of cell number (DNA content) and cell mass (protein content), depending upon the serum androgen concentration. See Y. Okuda et al., 145 *J Urol.*, 188–191 (1991), the disclosure of which is herein incorporated by reference. Therefore, measurement of organ wet weights is sufficient to indicate the bioactivity of androgens and androgen antagonists. In immature
15 castrated rats, replacement of exogenous androgens increased the weights of the ventral prostate (VP), the seminal vesicles (SV), and the levator ani (LA) in a dose-dependent manner as shown in Table 4.
